Exam

Calculator is ok. One A4 of handwritten notes.

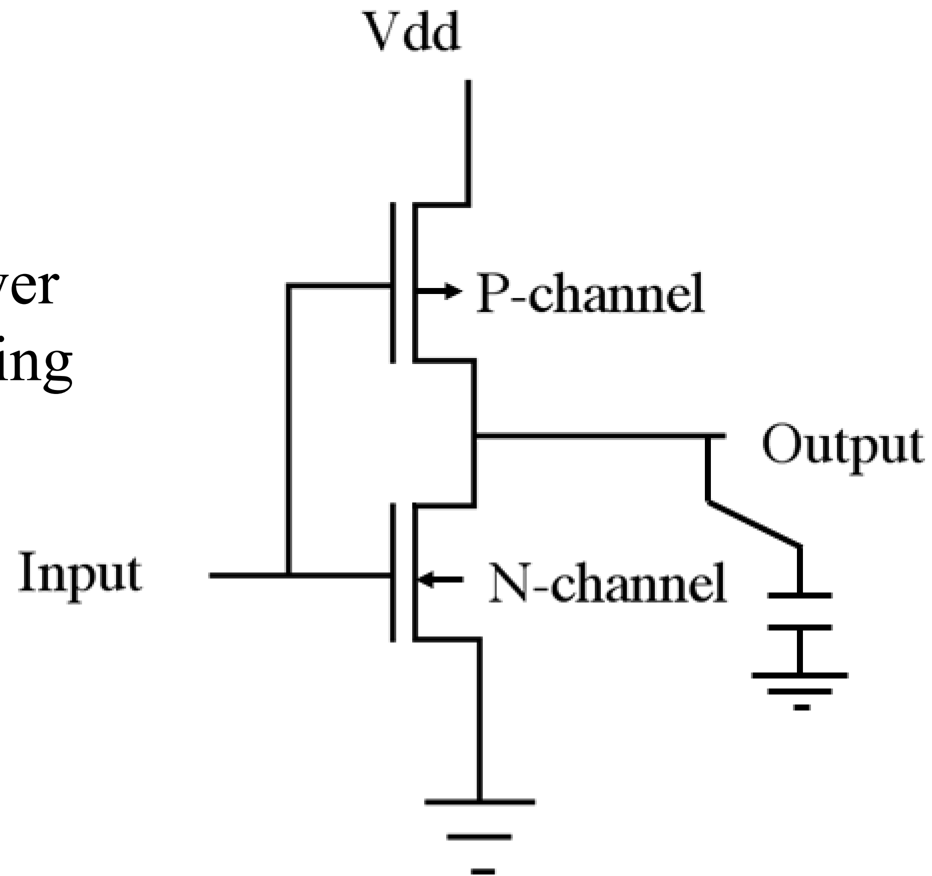
Explain some concept:
(tunnel contact, indirect band gap, thermionic emission, inversion, threshold voltage, ...)

Perform a calculation:
(concentration of minority carriers, integrate charge density to find electric field, ...)

Explain how a device works:
(JFET, MESFET, MOSFET, laser diode, bipolar transistor, LED, Schottky diode, Heterojunction bipolar transistor, ...)

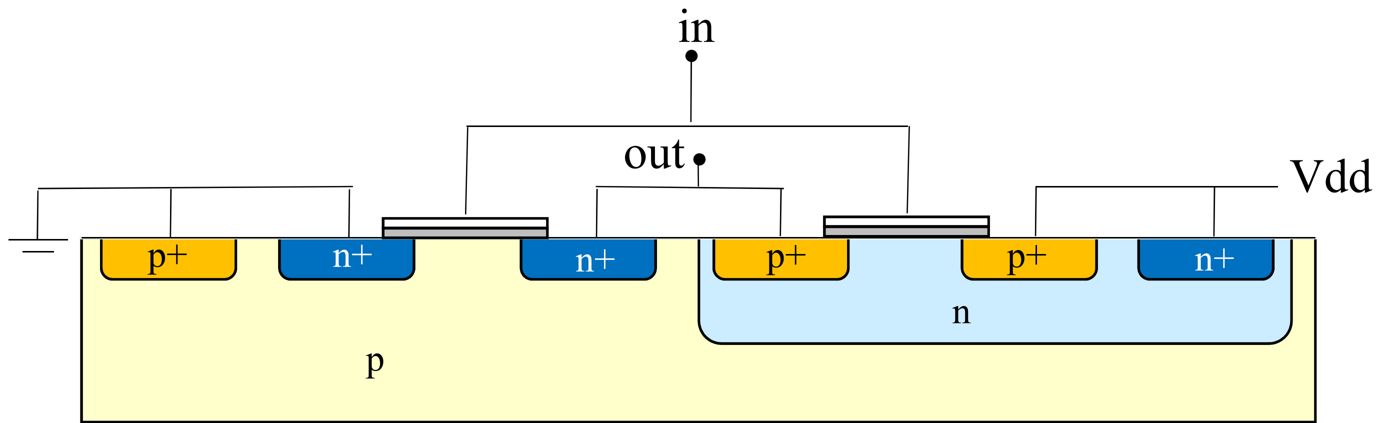
CMOS inverter

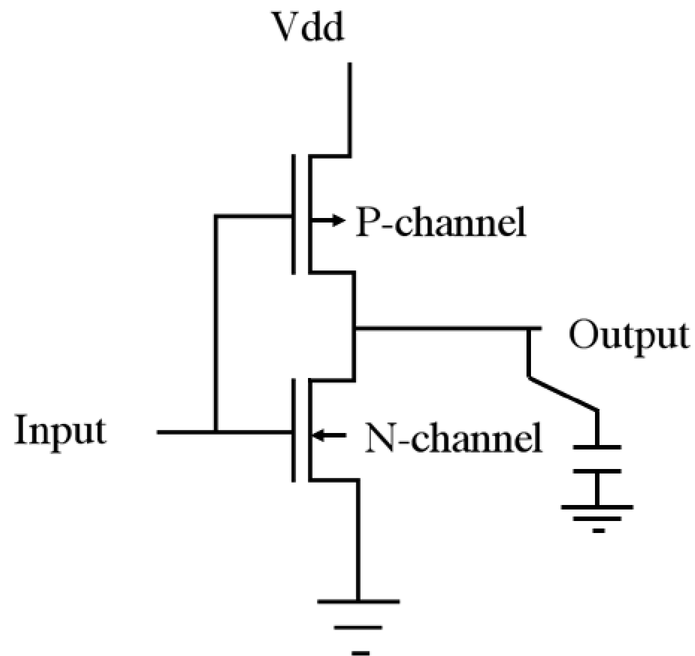
Dissipates little power
except when switching

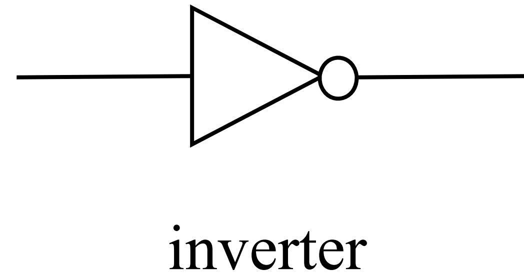


$$E = QV_{dd} = CV_{dd}^2$$

CMOS inverter

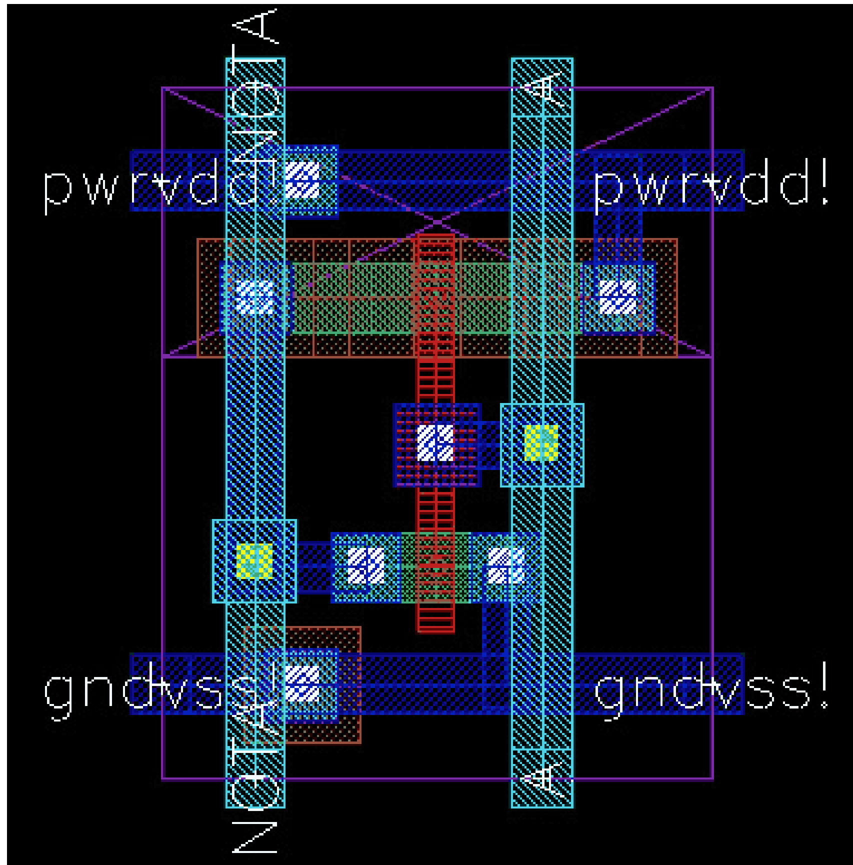


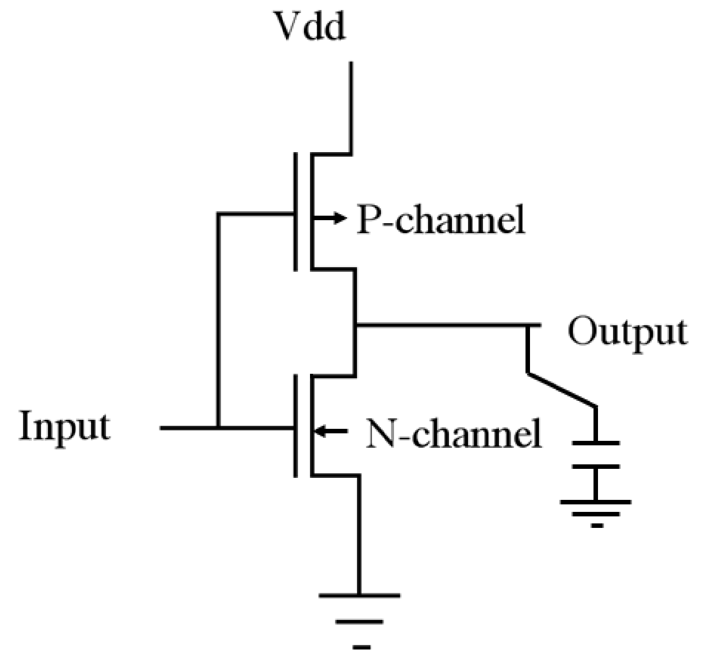


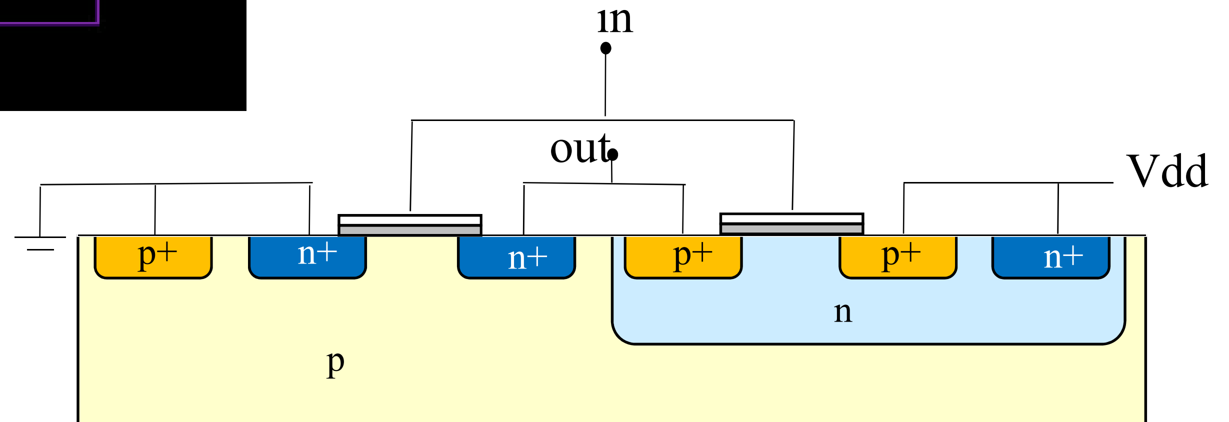


inverter

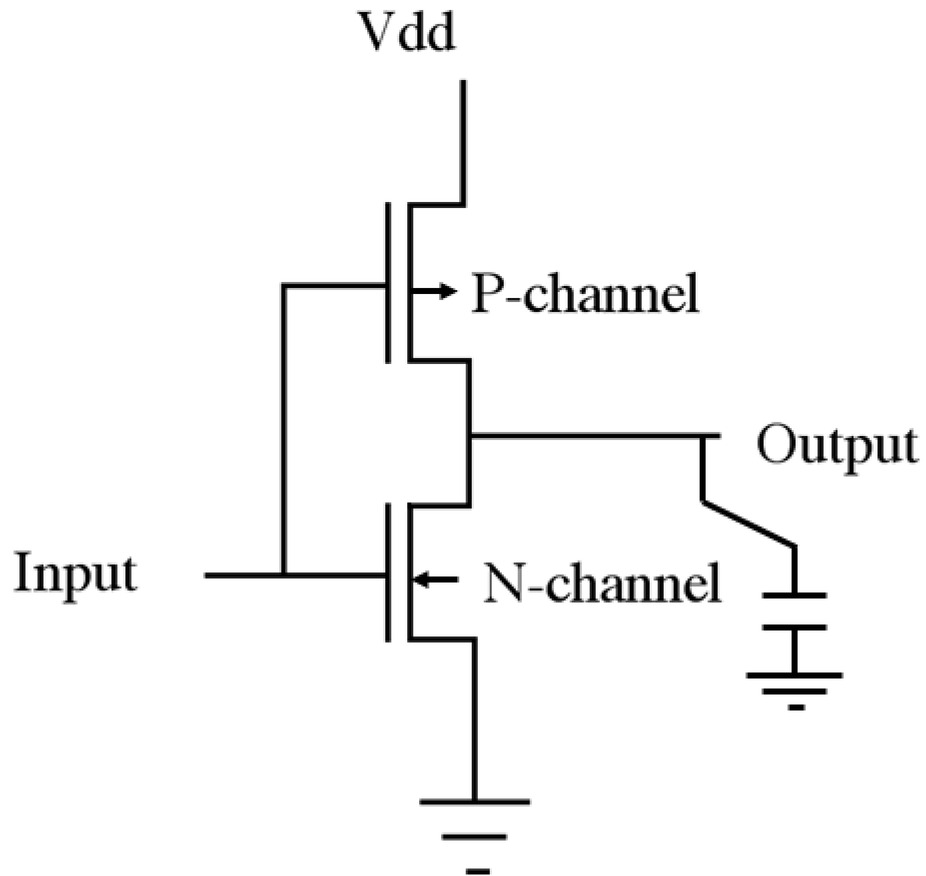
CMOS inverter



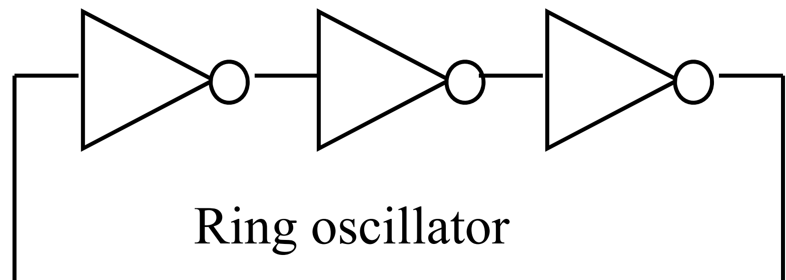




Gate delay

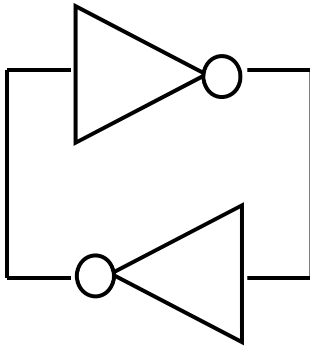


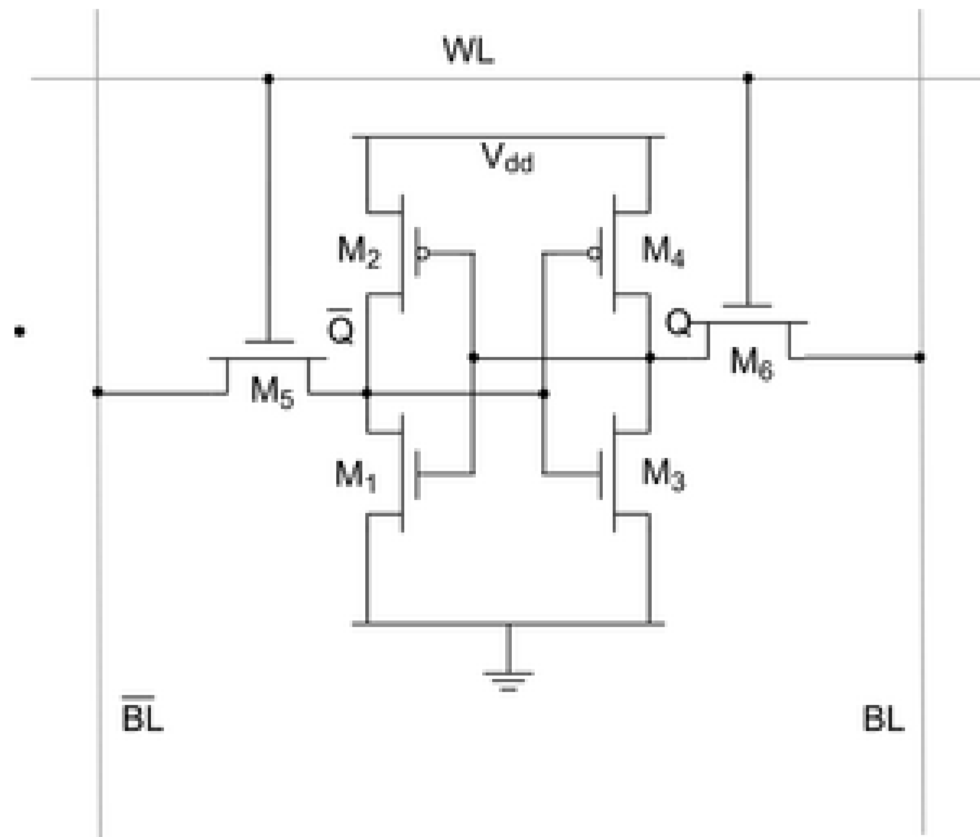
Gate delay is limited by $C_{gate}V_{dd}/I$.



SRAM

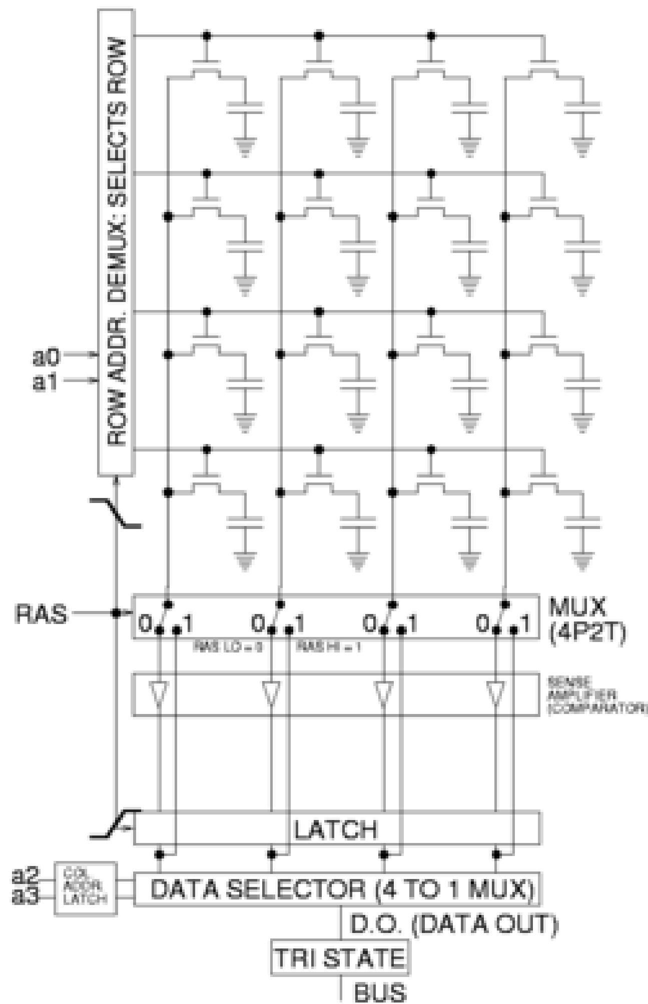
Static random access memory





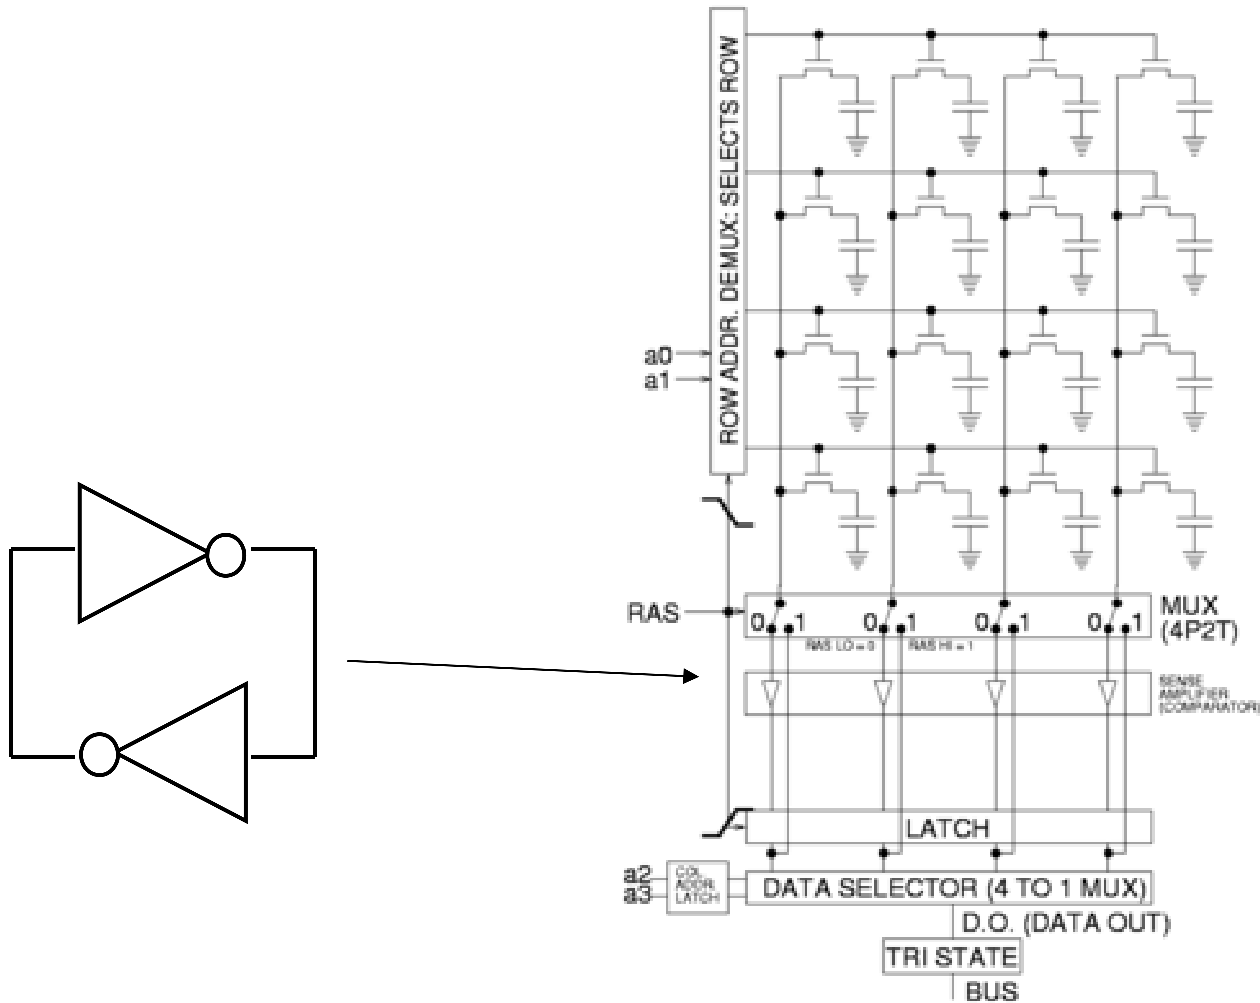
DRAM

Dynamic random access memory

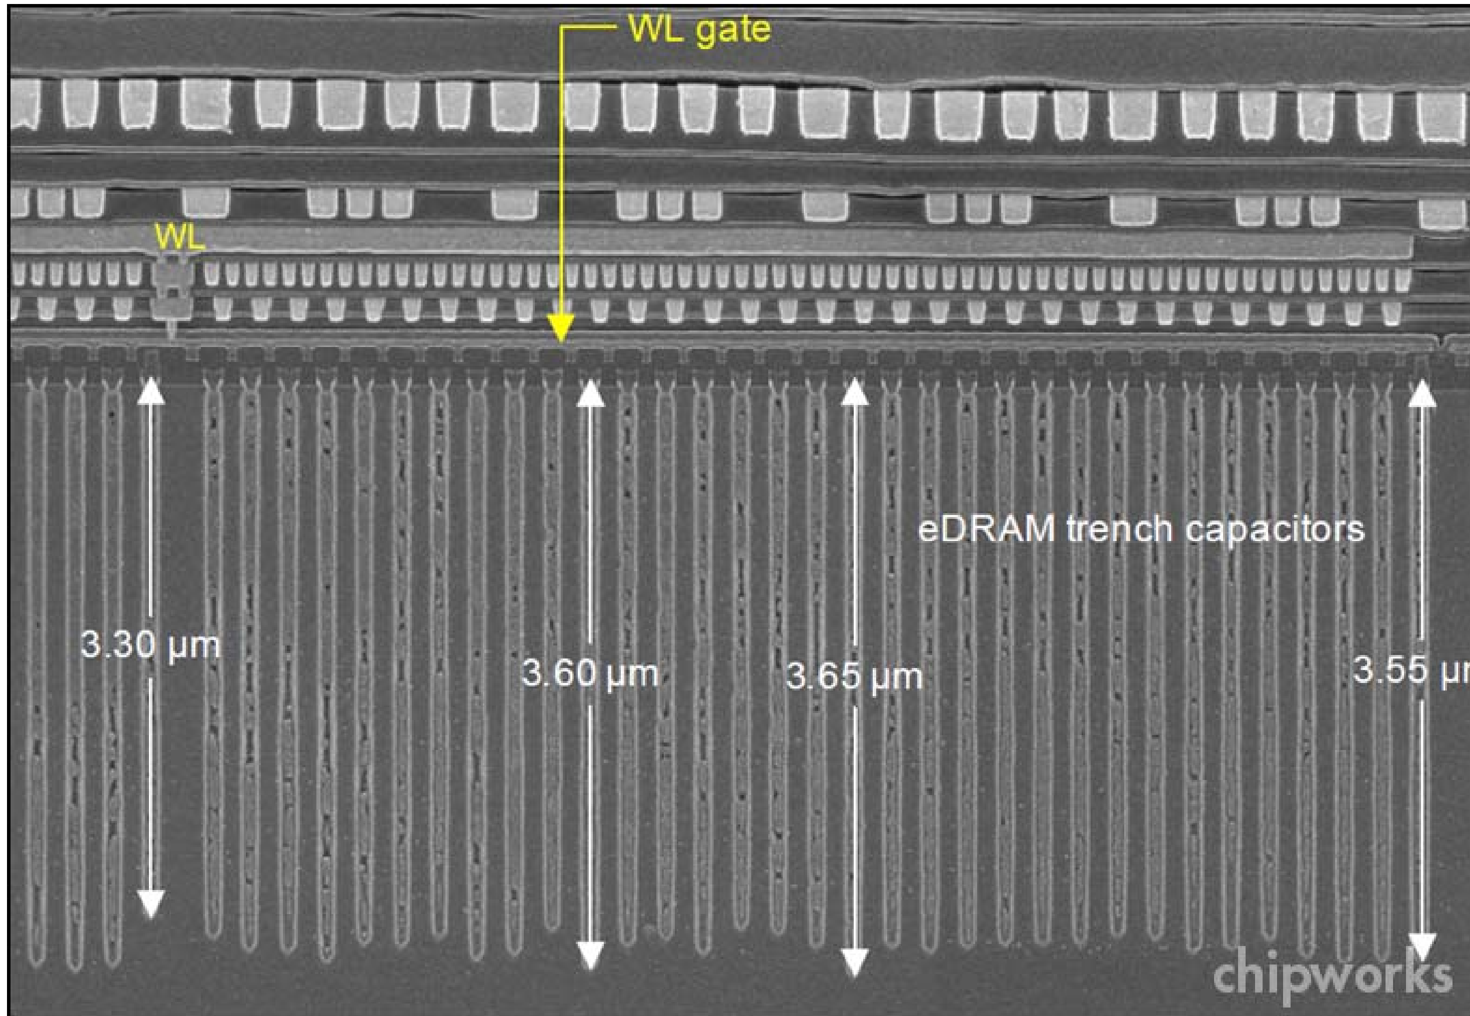


DRAM

Read and refresh DRAM with a SRAM cell



DRAM

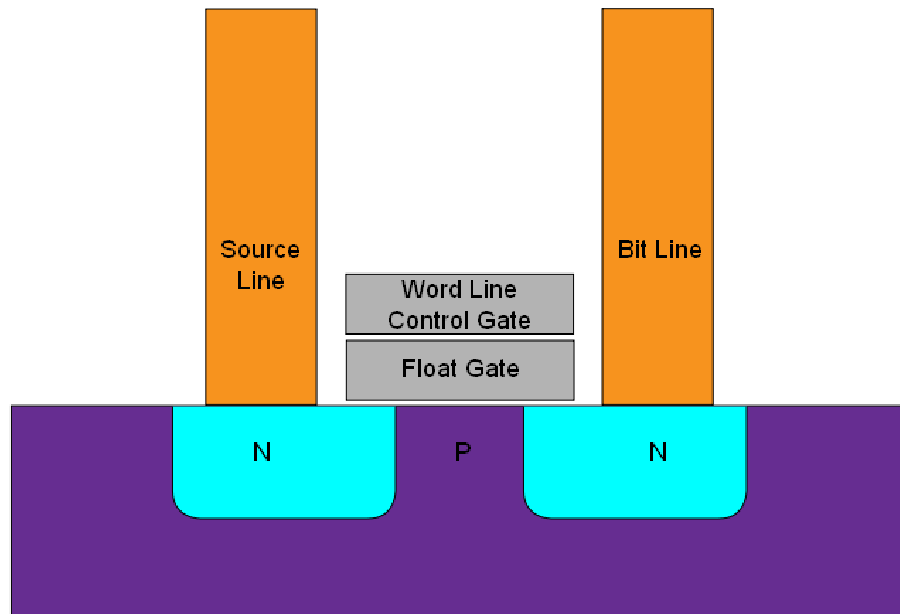


75:1

Silicon oxynitride SiO_xN_y dielectric

http://electroiq.com/chipworks_real_chips_blog/

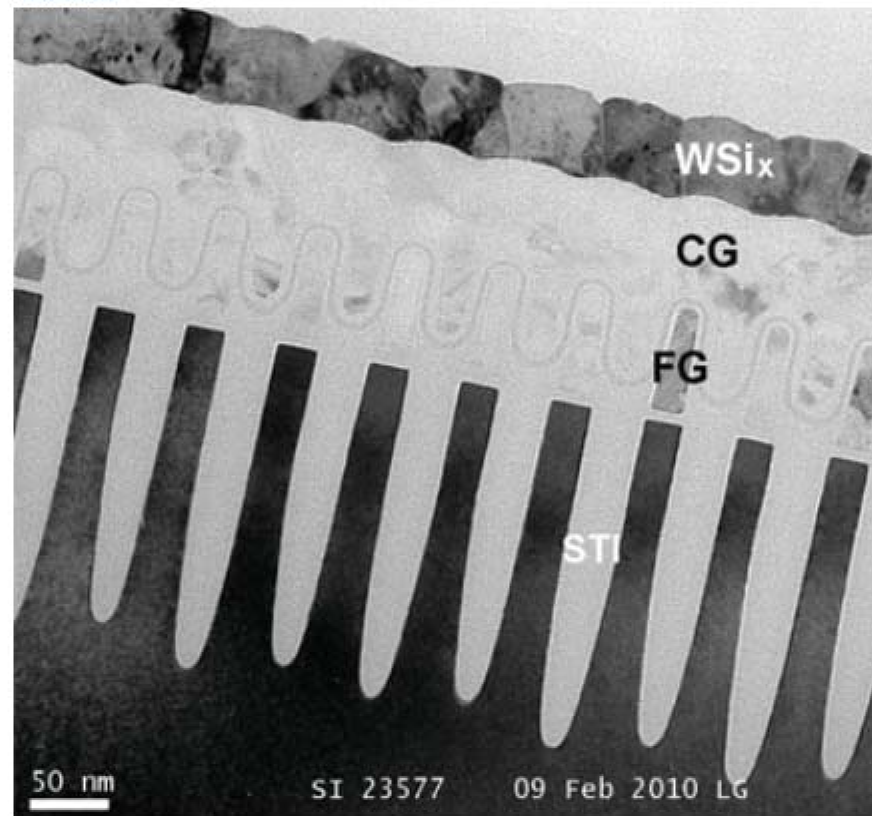
Flash memory



Charge is stored on a floating gate

nonvolatile

Intel Micron Flash Technologies (IMFT)
Shallow Trench Isolation (STI)
Control Gate (CG)
Floating Gate (FG)
Self-Aligned Doubled Patterning (SADP)



Topographical SEM image of the IMFT 25-nm flash memory array at gate level: array trench depth is shallower to allow a denser flash array

The extent of immersion-lithography tool usage cannot be known, but our end-of-the-wordline analysis and STI pattern analysis of the IMFT device has shown some interesting spacing patterns that could give useful insight into the lithography and SADP processes. Technically, immersion lithography is the mainstream technology for NAND flash integration for sub-50 nm and is used along with SADP to shrink line widths and avoid overlay issues. Strongly enhanced DP (two exposures + spacer approach) could extend immersion to 21 nm and beyond. Since the extreme ultraviolet lithography (EUVL) tool is not going to be ready till 2012, immersion would continue to fill the gap up to 2x-nm node and beyond.

Tunneling through an arbitrarily shaped potential barrier

In quantum mechanics, there is some probability that a particle of mass m will tunnel through a potential barrier even if the energy of the particle is less than the energy of the barrier. During a direct tunneling process, the energy of the electron remains contant. The form below calculates the transmission coefficient for tunneling. The shape of the tunnel barrier can be arbitrarily defined in the interval between $x = 0$ and $x = a$. The potential is assumed to be constant to the left of the tunnel barrier at the value $V(x=0)$ and constant to the right of the barrier at the value $V(x=a)$.

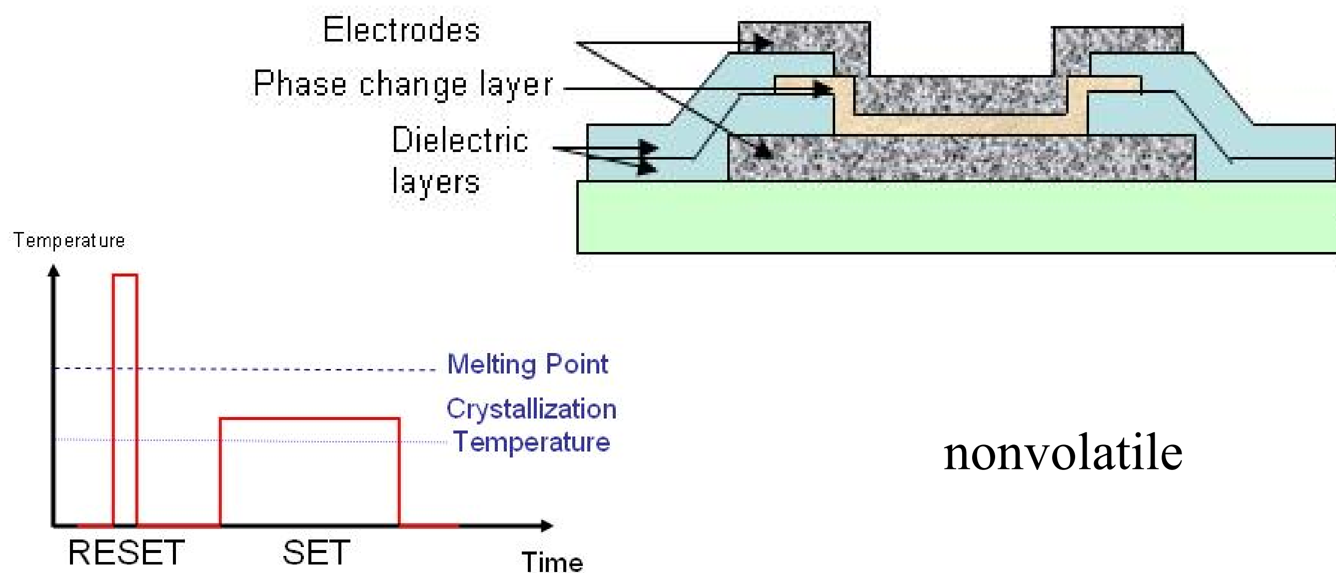
Phase change memory

Phase-change memory (PCM) uses chalcogenide materials. These can be switched between a low resistance crystalline state and a high resistance amorphous state.

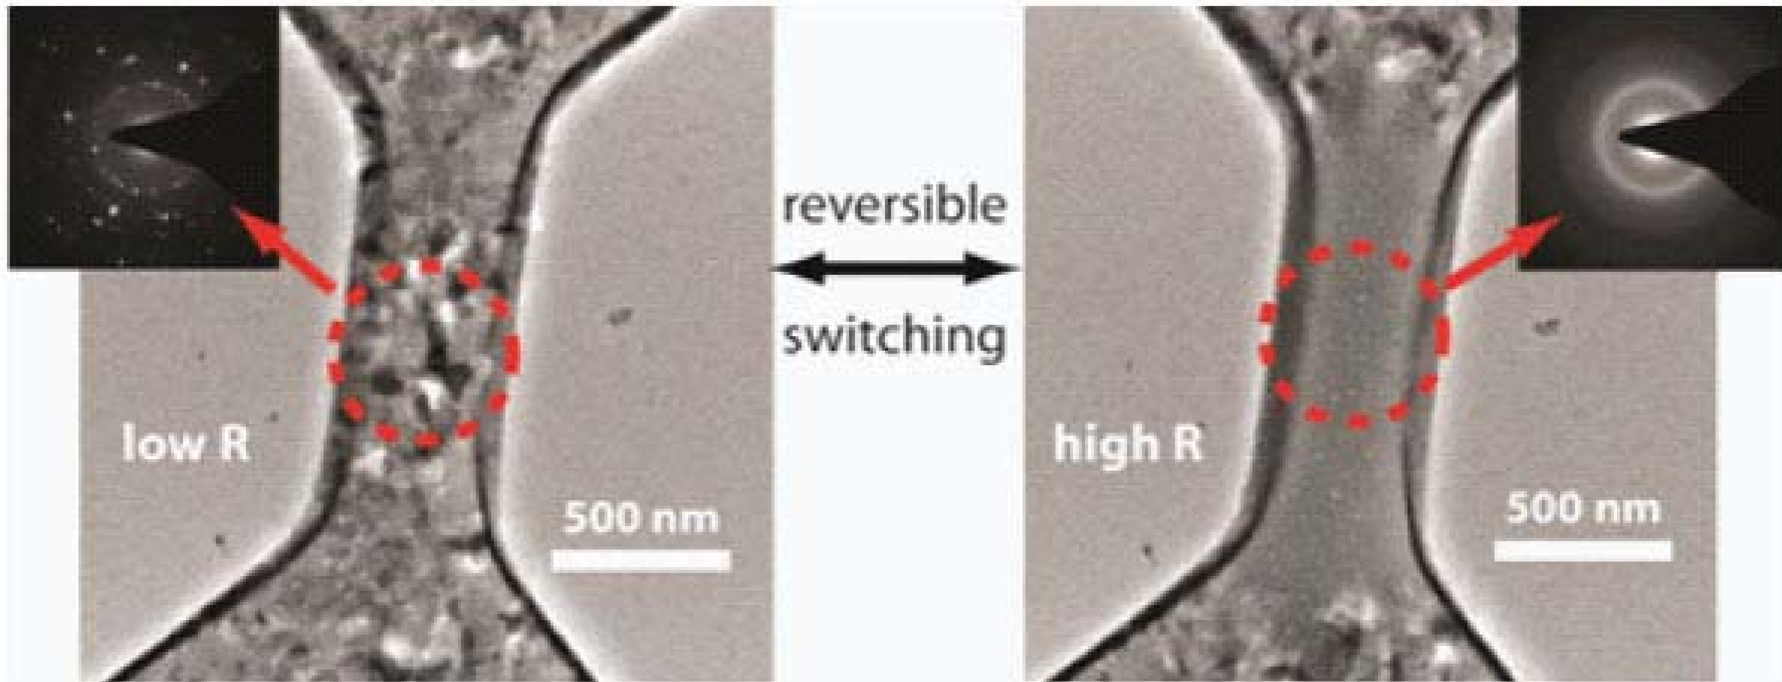
GeSbTe is melted by a laser in rewritable DVDs and by a current in PCM.



nonvolatile

Phase change material

Electron diffraction in a TEM of a GeSbTe alloy.

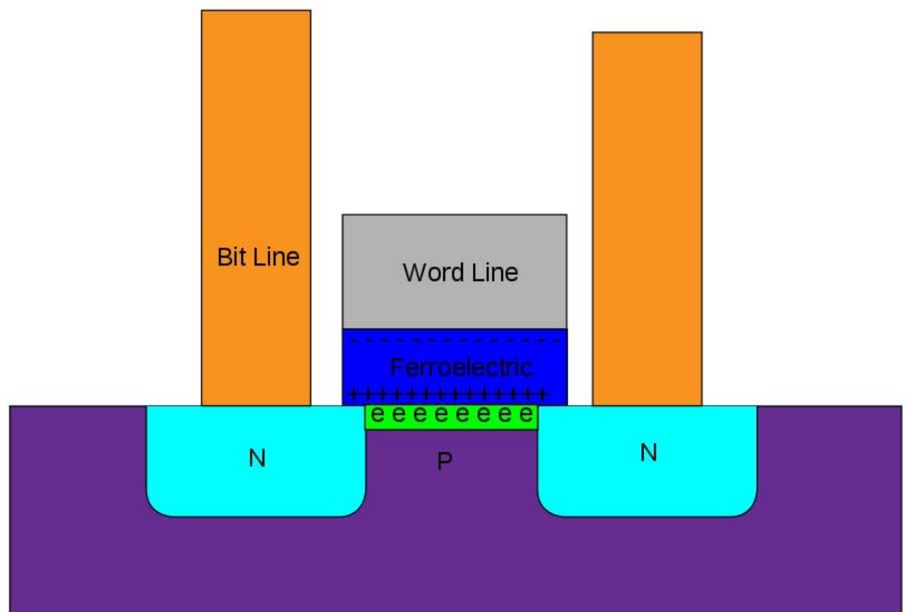


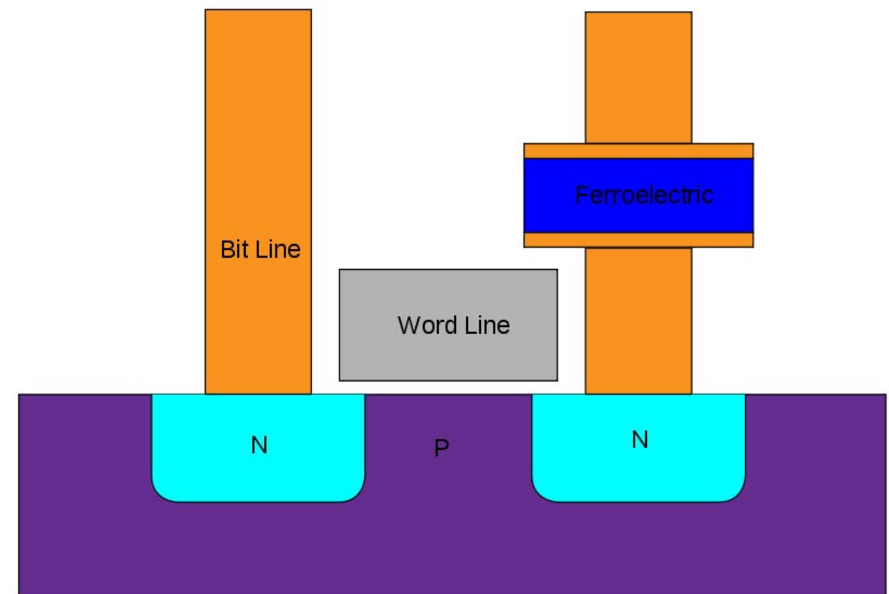
http://web.stanford.edu/group/cui_group/research.htm

Ferroelectric RAM

FeRAM uses a Ferroelectric material like PZT to store information.

Sometimes used in smart cards.

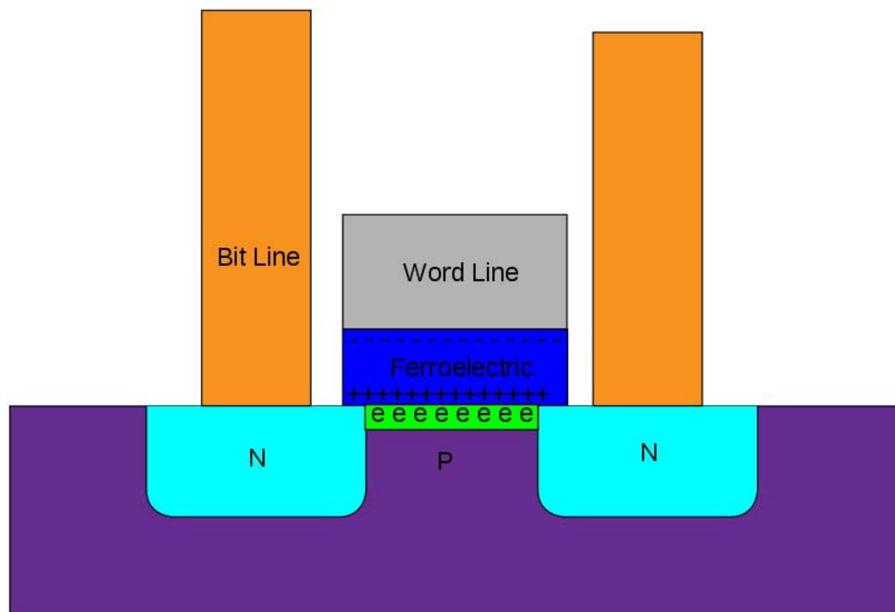


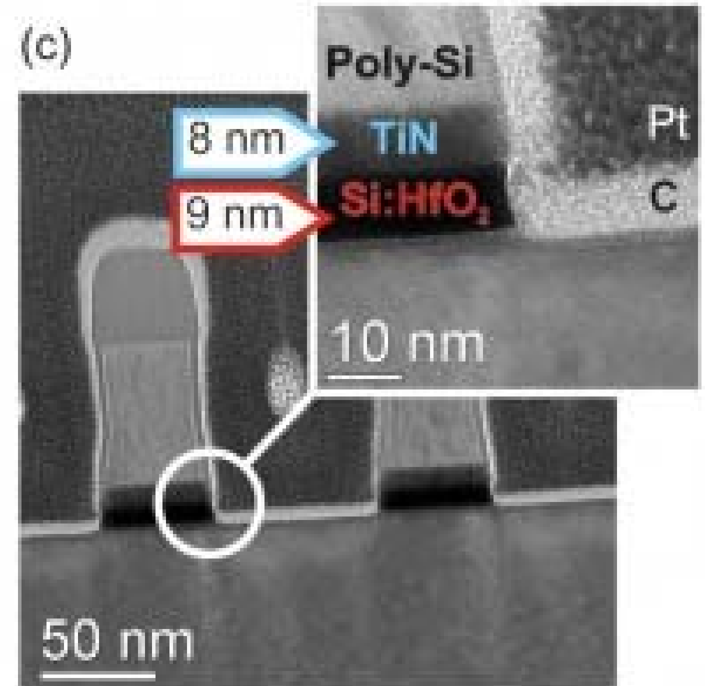


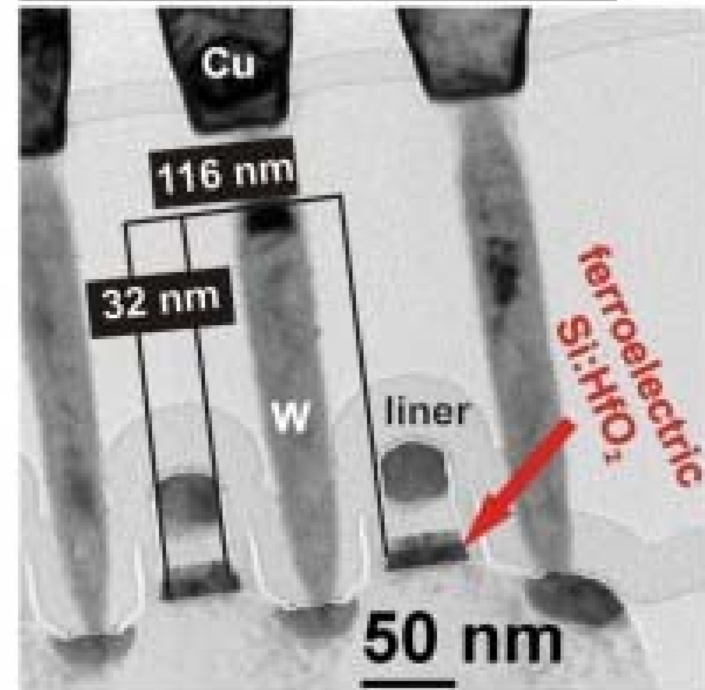
nonvolatile

To read, try to write a 0,
if a current flows, it was a 1.

Ferroelectric RAM



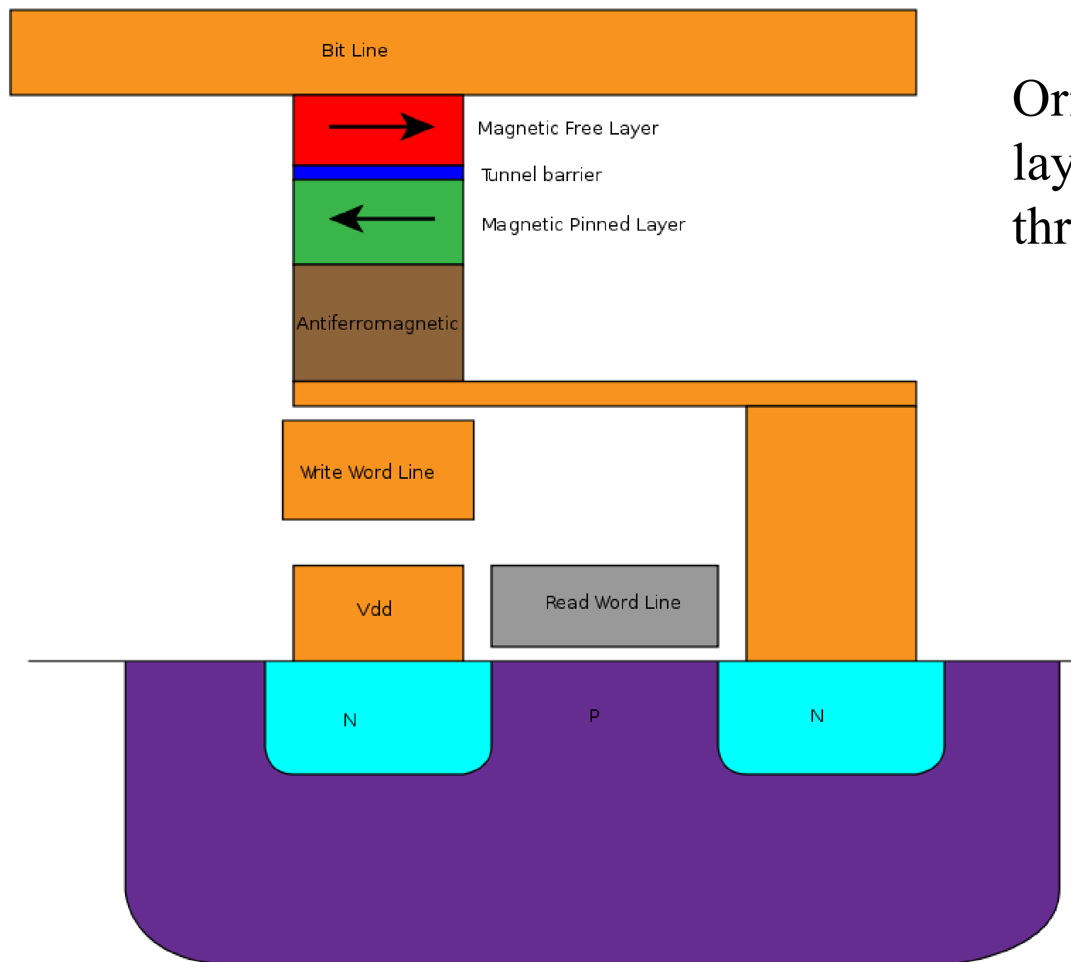




http://baldengineering.blogspot.co.at/2013_12_01_archive.html

Magnetic memory

In MRAM the resistance depends on whether the magnetic layers are parallel or antiparallel.

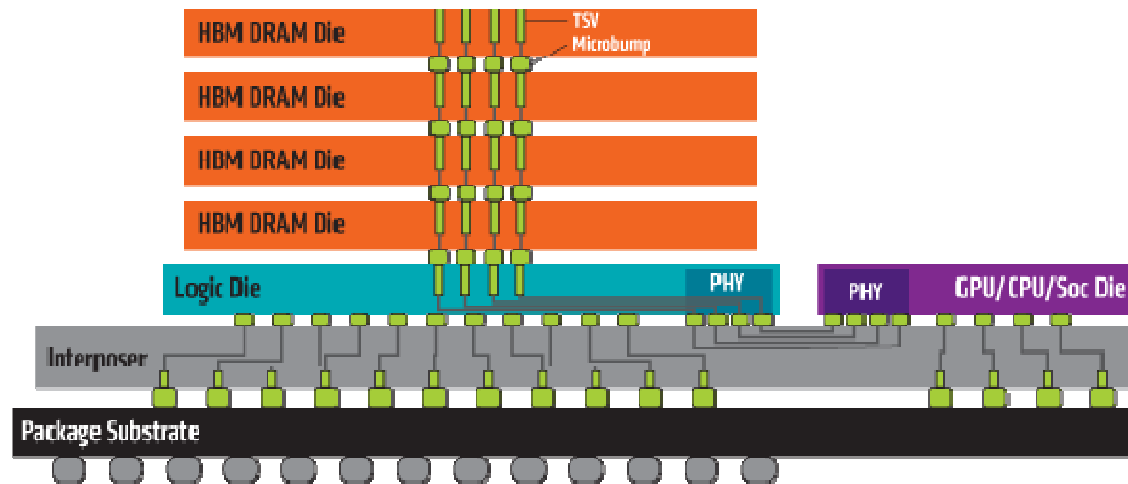


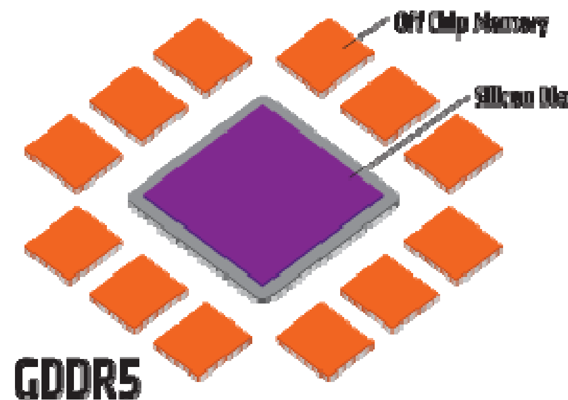
Orientaion of the magnetic free layer is set by sending a current through the bit and word lines.

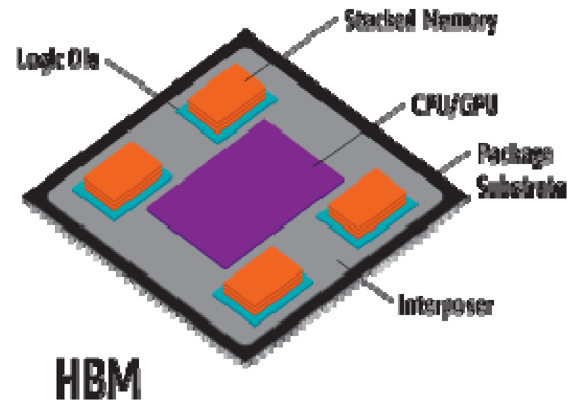
nonvolatile

High Bandwidth Memory

AMD to launch its HBM graphics cards on 16 June 2015.

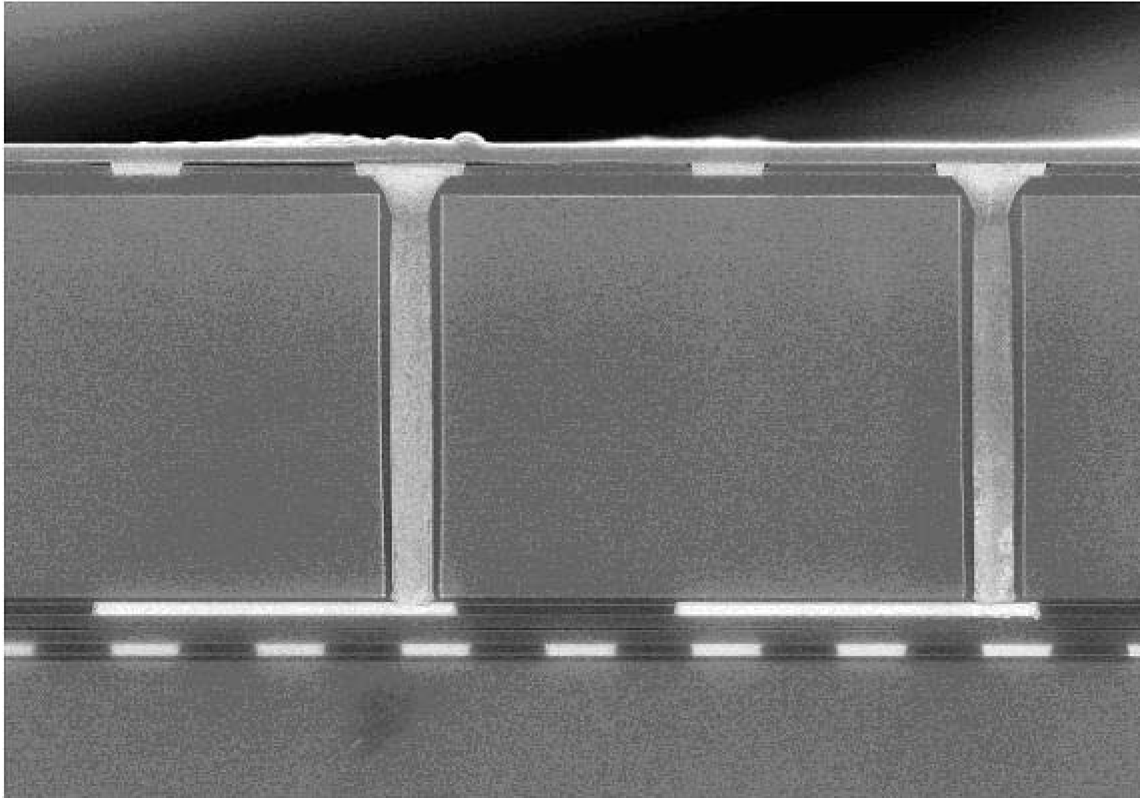






Through-Silicon Via (TSV)

http://javier.esilicon.com/2011/01/30/thru-silicon-vias-current-state-of-the-technology/



A vertical electrical connection (via) passing completely through a silicon wafer.

Used in 3D integration.

Bosch process

Repeat 2 processes over and over

1. Etch Si with SF_6 (nearly isotropic)

2. Deposit passivation layer C_4F_8

Directional etching at the bottom breaks through the passivation layer.

Short cycles: smooth walls

Long cycles: fast etching
